# Use of color\_seq.pl, color\_nums.pl, and color\_cols.pl scripts

Ryan Koehler 9/27/15 ryan@verdascend.com

## **Background and overview**

The scripts *color\_seq.pl, color\_nums.pl, and color\_cols.pl* are simple command line filters intended to colorize specific value-associated "words" contained within simple ASCII text. This is useful to highlight specific values for quick value identification and pattern visualization. The tools take text from a file or standard input then output this with ANSI escape sequences interjected to color specific characters in a terminal display. The tools also accept various command line options to allow user control over character or token selection and color choice.

This document briefly describes options available for these tools and, probably more importantly, provides example uses. Given that the point of these tools is to colorize text, examples are accompanied by screen captures illustrating outputs. (And this documentation is in pdf format to allow these graphics).

color\_seq.pl is for coloring DNA sequences. The default behavior is to color what appears to be sequences with a four-color scheme associated with A C G and T. The script contains logic to guess whether a "word" (or token; continuous block of characters) is sequence-containing or not based on the fraction of ACGT characters; Words deemed to not be sequence-containing are not colored. By default, entire lines beginning with "#" or ">" are not colored, as these traditionally are associated with comments or the header lines of fasta format files. This behavior can be changed via command line switch.

In addition to simply finding and coloring DNA sequences, *color\_seq.pl* can be used to highlight attributes often encountered in sequence files. For example, lower case sequence can be ignored (i.e. not colored), or upper and lower case sequence can be differentiated by bold / non-bold coloring. Another use is to highlight non-ACGT characters within (what appears to be) sequence. This is useful to quickly find IUB characters and any non-sequence characters (both colored differently to stand out).

Finally, *color\_seq.pl* can be used to highlight *window-based* sequence features. With this feature runs of contiguous characters containing, as well as not containing, a specific base are highlighted. This feature supports IUB degenerate codes in addition to the normal ACGT bases. For example, using window-based highlighting on can readily identify runs of GC (IUB code "S"), runs of purines (IUB code "R"), etc. In addition to highlighting windows containing the specified base (or bases corresponding to an IUB code), windows *not* containing runs of the chosen base(s) are also highlighted in a second color.

*color\_nums.pl* is for coloring numbers. The default behavior is to highlight numbers within text using a single color (This is distinct from simply coloring numeral characters). By default, entire lines beginning with "#" are not colored, as these traditionally are associated with comments, but this behavior can be changed via command line switch. It is also possible to only color a subset of number-containing "columns" via command line switch.

Assigning colors based on value allows rapid identification of "high" or "low" values. In addition, coloring a whole table of numbers together can serve as s simple means to visualize patterns in the data.

color\_cols.pl is for coloring columns so that different columns (e.g. "fields" in a data table) may be readily identified. The default behavior is to cycle through a set of colors for odd number columns and leave even number columns white, such that the cycle repeats every ten columns. Other schemes and cycling frequencies are available (e.g. every 5 or 2 columns), a range of columns to color may be specified, and specific columns may be selected for coloring. By default, entire lines beginning with "#" are not colored, as these traditionally are associated with comments, but this behavior can be changed via command line switch. It is also possible to specify that columns are separated by tabs rather than the default spaces.

# Use of *color\_seq.pl*

Calling *color\_seq.pl* without any arguments (or with "-help" or an unrecognized argument) yields this splash / help screen:

Each command line switch has a brief description of what it does. Given only input and no command switches, default coloring is performed. Figure 1 shows a test-case sequence file displayed via the *cat* command. Figure 2 shows this same content with output from *cat* piped through *color\_seq.pl*, which is given a "naked dash" to indicate input is from standard input (*stdin*). Other color schemes may be specified with the <code>-cabi</code> and <code>-cgc</code> switches. The result of these is shown in Figure 3, with "ABI" style first and GC-based coloring second.

Figure 1. Test-case sequence file.

**Figure 2.** *color\_seq.pl* Default coloring. Test-case sequence 'piped' as input. The command switch '-' is used to indicate input will come from *stdin*.

```

**Figure 3.** *color\_seq.pl* ABI and GC-based coloring schemes.

Some options can be combined, such as the -1w and -all switches, which, respectively, direct the script to color lowercase characters white (i.e. do not color them) and to include all

lines (i.e. do not ignore lines starting with ">" or "#"). The result is shown in Figure 4, which uses the default color scheme. Note that the "ACGT" in the comment on the first line is colored, while the lowercase sequence characters on the third line (and further down) are not. Highlighting non-ACGT within sequence-like strings is showin in Figure 5 with the <code>-nacgt</code> switch. Normal ACGT bases are not colored, IUB code letters are colored red, and other (non-DNA) characters are colored cyan.

**Figure 4**. *color\_seq.pl* Changing which characters are considered for coloring. The <code>-lw</code> and <code>-all</code> switches result in no color for lower case characters, and all lines being "colorable", respectively.

**Figure 5**. *color seq.pl* Highlighting non-ACGT characters within sequence-containing strings.

Highlighting *window-based* sequence features is shown in Figure 6. Contiguous runs of specified base characters, and runs *devoid* of these, are colored within sequence-containing

strings, while the remaining sequence characters are not colored. Two parameters define windowing behavior: base type and window size. Base type may be ACGT or any IUB code. Window size dictates the minimal length of runs that qualify for coloring. Runs of selected bases (and non-selected bases) that are at least window size long are colored; Selected base type(s) are red, and non-selected base type(s) are cyan.

**NOTE**. Only ACGT bases qualify for selection and lines are considered independently. This means that IUB characters within strings do not count for runs, and runs spanning multiple lines are not colored.... (Maybe in a future version???)

**Figure 6**. *color\_seq.pl* Coloring windows with like-base runs. Red denotes selected base type(s) and cyan denotes *absence* of selected base type. Top example highlights runs of purine bases (A or G) in red, indicated by IUB code "R", using default window size ( = 5). Bottom example highlights runs of C, with window size given as 3.

# Use of *color\_num.pl*

Calling *color\_num.pl* without any arguments (or with "-help" or an unrecognized argument) yields this splash / help screen:

Each command line switch has a brief description of what it does. Given only input and no command switches, default coloring is performed. Figure 7 shows the first five lines of three number-containing files displayed via the *head* command. Figure 8 shows this same content with output from *head* piped through *color\_num.pl*, which is given a "naked dash" to indicate input is from standard input.

Specific number values can be highlighted. For example, the -rg switch can be used to specify a range of values; Numbers within the range are shown with one color, numbers less than the range are shown in another color, and numbers more than the range are shown in still another color. It is also possible to highlight *only* the within-range values using the -ok switch. Figure 9 shows this behavior, using a chosen range of 69 to 71. There are also options to differentiate only two classes of numbers; Those with values greater than or less than some chosen threshold and the rest.

```

Figure 9. color\_nums.pl Specifying a range of values to highlight (e.g. 69 to 71).

To better highlight specific numbers, subsets of (potentially) number-containing tokens may be ignored. Only values found in a range of columns can be colored, thus allowing some number-containing columns to be easily ignored. Column selection is done with the <code>-col</code> switch, which is associated with two number to specify start and end columns. Use of the <code>-not</code> switch inverts column selection criteria, so that numbers within selected columns are *not* colored but numbers in other columns may be colored. The <code>-iz</code> switch allows zero values to be ignored. Figure 10 shows the result of combining all three above mentioned options, in this case selecting all columns *except* column 5, specifying a coloring range from 2 to 3, and ignoring zeros.

```

**Figure 10**. *color\_nums.pl* Selecting specific columns, ignoring zero values and coloring by value range. All columns except column 5 are selected via the combination of switches <code>-col 5 -not</code> and zeros are ignored (i.e. not colored) because of the <code>-iz</code> switch. Finally, a color range of 2 to 3 is specified for differential value-based color assignment (i.e. in range values are yellow; under range values are blue; over range values are red).

Options for predefined ranges include the -nr switch for 0 to 1, and the -n2 switch for -1 to 1. Figure 11 shows an example.

# Use of *color\_cols.pl*

Calling *color\_col.pl* without any arguments (or with "-help" or an unrecognized argument) yields this splash / help screen (which includes colors to illustrate cycling patterns):

```
verdascend [~/git/comline_color_tools] 40> ./color_cols.pl
color cols.pl V0.2; RTK 3/21/15
Usage: <infile> ['-' for stdin] [...options]
 <infile>
            Text file (e.g. data with 'word' tokens)
            Mark col # (Note: 1-based index on tokens)
  -m #
            Step; Mark every #'th col
  -s #
  -col # #
            Limit coloring to cols # to #
            Separate columns by tab (default is space)
  -tab
            Invert col qualifications
  -not
  -2c
            Two color scheme: Cycle 1 2
            Five color scheme: Cycle 1 2 3 4 5
  -5c
            Ten color scheme: Cycle 1 2 3 4 5 6 7 8 9 10
  -10c
            Color all lines; Default ignores comment '#'
  -all
```

Figure 12. color\_cols.pl Splash / help screen.

Each command line switch has a brief description of what it does. Given only input and no command switches, default coloring using the "-10c" pattern is performed. Figure 13 shows the the default coloring scheme, as well as two others ("-2c" and "-5c", which cycle every two and five columns, respectively), using the test file "test-lod.mat". Figure 14 illustrates the "mark" and "step" arguments, and Figure 15 illustrates selection of column ranges for application of color. Columns use a 1-based counting scheme and ranges are inclusive.
